

LAB 23: PERITONEAL CAVITY AND SUPRACOLIC REGION

— Goals

- 1 Survey the GI organs.
- 2 Examine the peritoneum, peritoneal cavity, mesenteries, omenta, and peritoneal ligaments.
- 3 Locate the subparts of the greater sac.
- 4 Study the lesser omentum and demonstrate the lesser sac.
- 5 Dissect the celiac trunk and demonstrate its branches.
- 6 Clean and study the organs in the supracolic region: liver; gallbladder and biliary tracts; stomach; duodenum; pancreas; and spleen.
- 7 Demonstrate the structures that make up the portal triad.
- 8 Remove the liver and examine its features.

ANTERIOR ABDOMINAL WALL

The anterior abdominal wall has been opened for you (thank you, first-year students!)

Inspect the internal aspect of the inferior abdominal wall.

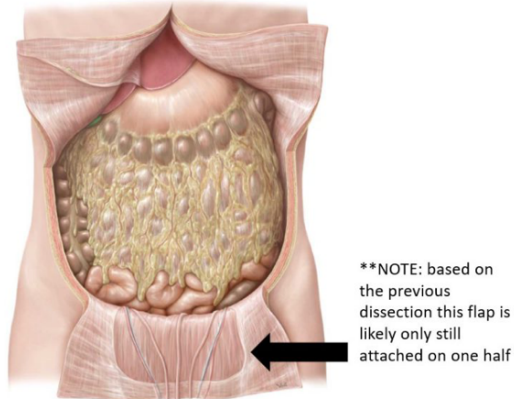

Figure 23.1.

COMPLETE ANATOMY POSTERIOR SURFACE OF ANTERIOR ABDOMINAL WALL

If there is a portion of the inferior abdominal wall intact, inspect the portion beneath the umbilicus to identify the **umbilical folds** and **umbilical ligaments**.

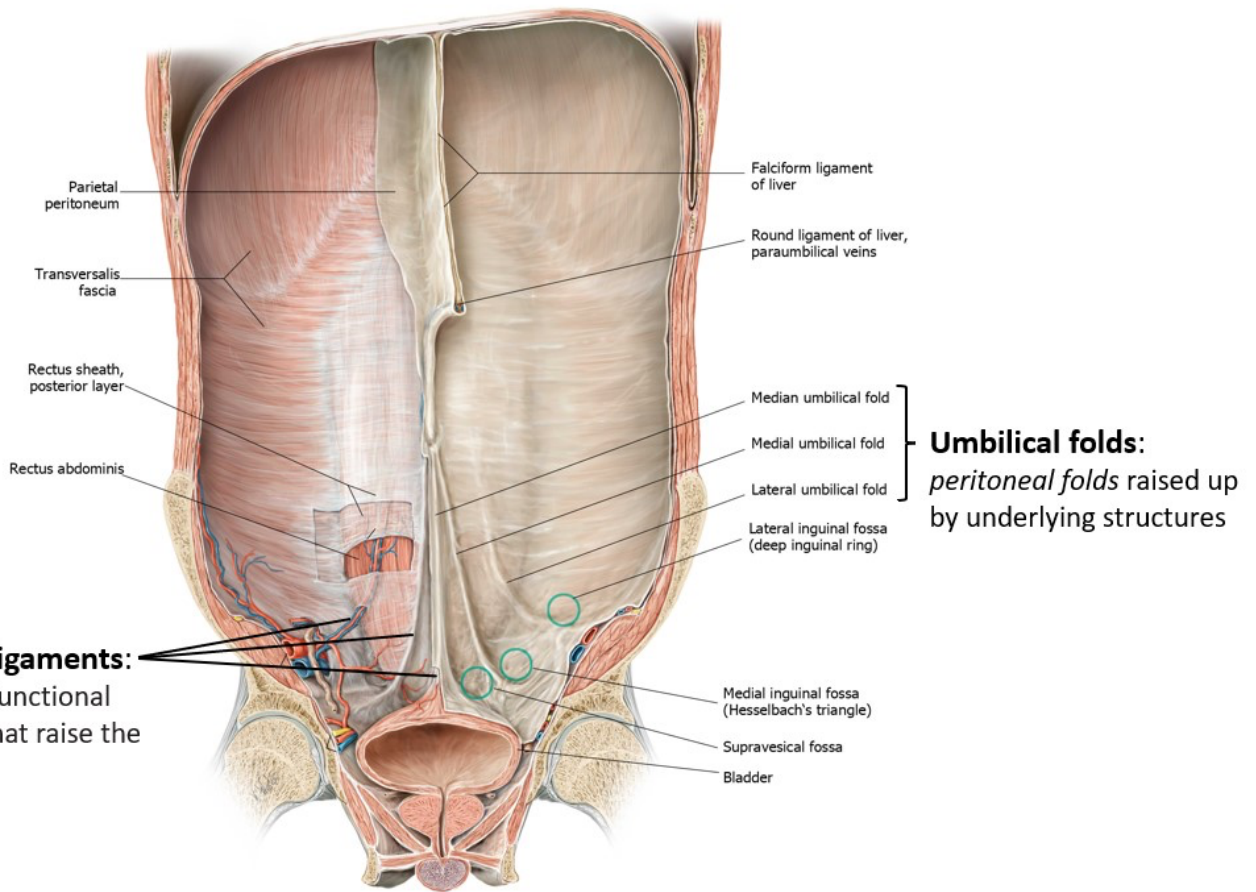

Figure 23.2.

Identify:

Median umbilical folds contain the **median umbilical ligament (urachus)**. This is a fibrous vestige of bladder development. Look for this descending down from the umbilicus along the midline.

Medial umbilical folds (left and right) contain the **medial umbilical ligaments**. These are the obliterated fetal **umbilical arteries**.

Lateral umbilical folds are more subtle, inconspicuous folds of peritoneum. They contain the **inferior epigastric vessels**.

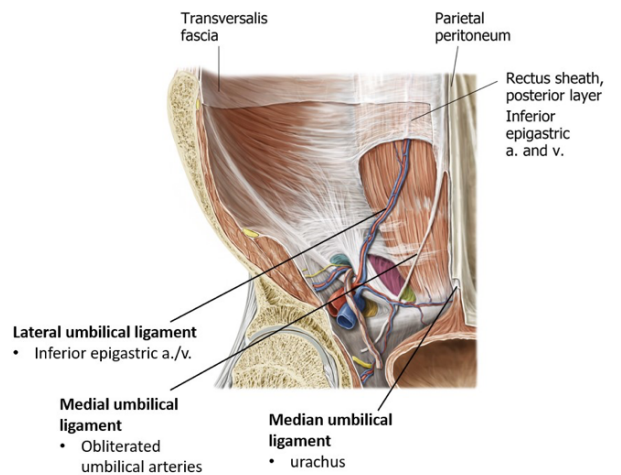

Figure 23.3.

Clinical correlation

Can you recall the role of the inferior epigastric vessels in determining direct vs. indirect inguinal hernias? Identify the borders of the **inguinal (Hesselbach's) triangle** from this internal surface.

On each side, the **inferior epigastric vessels** pass under the arcuate line to enter the rectus sheath, posterior to the rectus abdominis muscles. Within the rectus sheath, the inferior epigastric artery supplies the rectus muscle and anastomoses with the **superior epigastric artery**, a terminal branch of the **internal thoracic artery**.

This anastomosis could provide an alternate route for blood to reach the lower limb should the descending aorta be compromised.

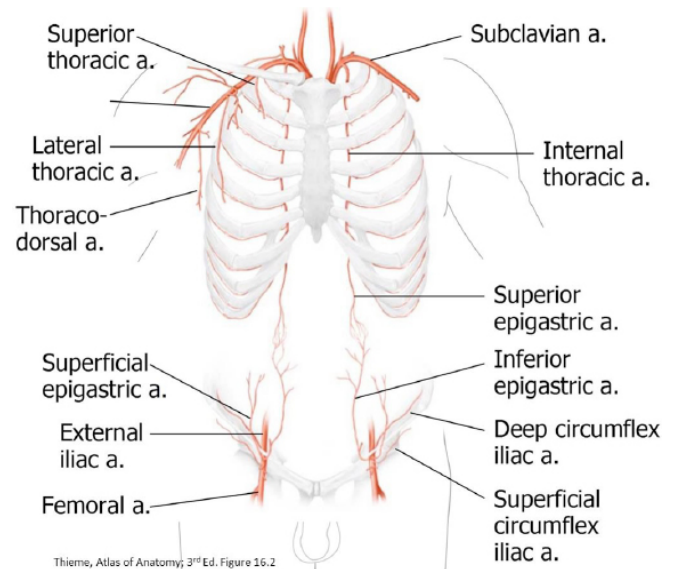

Figure 23.4. Anastomosis between thoracic and abdominal circulations.

Clinical correlation

Discuss this alternate route with your group. Draw a flowchart.

OVERVIEW OF ABDOMINAL VISCERA

Explore and name the organs of the abdominal cavity.

COMPLETE ANATOMY
ABDOMINAL VISCERA

Liver

The sharp **inferior border** peeks out under the costal margin; reach under the diaphragm to feel the liver's **diaphragmatic surface**. Identify the **right** and **left lobes** of the liver – covered in visceral peritoneum

Examine the sickle-shaped **falciform ligament running between the lobes**. This double layer of peritoneum connects the liver to the anterior abdominal wall (its attachment to the anterior wall has likely been cut). Palpate the arched inferior free margin of the ligament. The **cord-like** structure within the inferior margin of the ligament is the **round ligament of the liver** (remnant of the fetal **umbilical vein**).

Figure 23.5.

Elevate the liver to find the abdominal esophagus and the stomach. With your right hand, reach across the cadaver to the left side behind to stomach and under the diaphragm to find the **spleen**.

The **pancreas** is hidden deep to the stomach. It is covered by peritoneum (it is retroperitoneal) so it may be difficult to identify initially.

Figure 23.6.

Small Intestine

Trace the stomach to the right to find the **duodenum**. **Only the first part of the duodenum is visible (intraperitoneal)—you won't see parts 2, 3, and 4 yet because they are retroperitoneal.** It is curved and shaped like the letter C. The concavity of the curve faces to the left. Distal to the duodenum are the other parts of the small intestine: **jejunum** and **ileum**. Push the small intestine to the right to find the **duodenojejunal junction**. Trace the ileum to the right lower quadrant to find the **ileocecal junction**.

Large Intestine

Push the small intestine to the left to find the **ileocecal junction**. Now trace in order from proximal to distal: **cecum**, **appendix** (if present), **ascending colon**, **transverse colon** (lift **greater omentum** to see it), **descending colon**, **sigmoid colon**, and **rectum**. Notice how the large intestine forms a box around the small intestine.

PERITONEUM AND PERITONEAL CAVITY

Use your hands to explore the peritoneal cavity, spaces, omenta, mesenteries, and peritoneal ligaments.

Identify:

- **Parietal peritoneum** (on the body wall)
- **Visceral peritoneum** (on the organs)
- The **peritoneal cavity** is the space between the parietal and visceral peritoneum.

REALIZE that the peritoneal cavity is a “potential” space. In a living person, there is very little space between the parietal and visceral layers of the peritoneum. This space is occupied by a thin layer of serous fluid that lubricates the organs and body wall and facilitates their friction-less movements.

The two parts of the peritoneal cavity are the **greater sac** and the **lesser sac**. With the anterior abdominal wall laid open, you are looking into the greater sac.

Identify these subparts of the greater sac:

- **Sub-phrenic spaces** between the diaphragm and liver (this space is further subdivided by the falciform ligament)
- **Hepatorenal recess** (aka—**Morison’s pouch**) between liver and the right kidney
- **Paracolic gutters** (between ascending/descending colon and lateral wall)
- **Retrocecal recess** (sometimes the appendix hides here!)
- **Rectovesical pouch** in males—in the pelvis, between rectum and bladder
- **Recto-uterine pouch (pouch of Douglas)** and **vesico-uterine pouch** in females (IF there is a uterus present)—in the pelvis, between rectum and uterus, and uterus and bladder, respectively.

Clinical correlation

The peritoneal pouches in the pelvis are clinically important because they are the most inferior parts of the peritoneal cavity, so fluids can collect here.

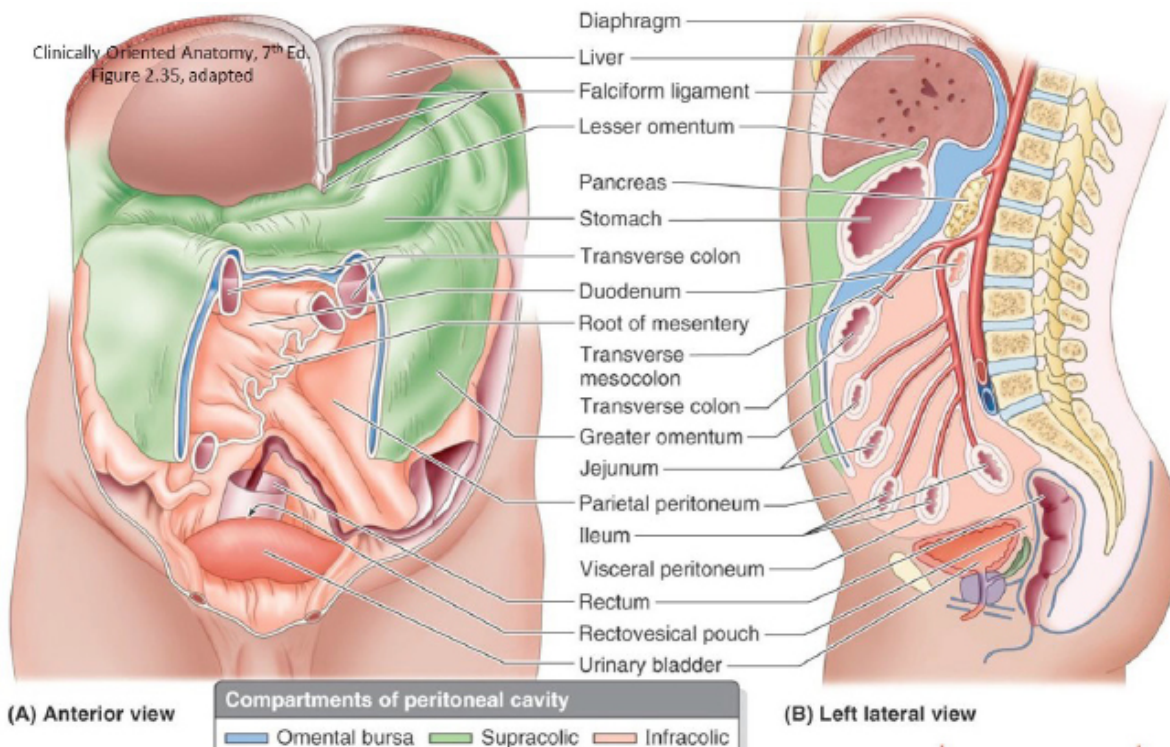

Figure 23.7.

Lesser Sac

Where is the **lesser sac**? To find it, first we need to identify the **lesser omentum**. The lesser omentum is a mesentery that attaches the liver above to the stomach and first part of the duodenum below.

COMPLETE ANATOMY OMENTA

The lesser omentum has two parts:

- 1 **Hepatogastric ligament** = very thin, almost transparent. Connects liver to lesser curvature of stomach.
- 2 **Hepatoduodenal ligament** = connects liver to first part of duodenum (the other parts of the duodenum are retroperitoneal). It is thick, because it contains the **portal triad**: the **hepatic artery proper**, the **bile duct**, and the **portal vein**. Feel the structures within the hepatoduodenal ligament between your thumb and finger.

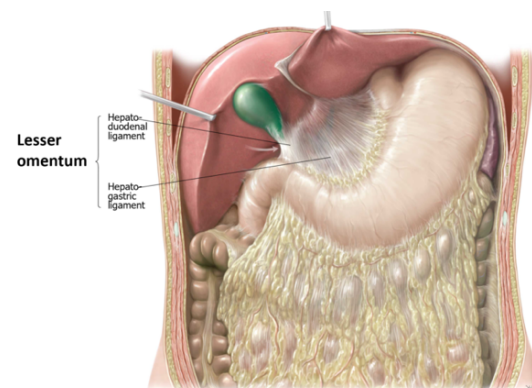

Figure 23.8.

Recall from embryology that the lesser omentum and falciform ligament are derived from the **ventral mesentery of the stomach**.

The **lesser sac (omental bursa)** is a blind pouch posterior to the lesser omentum and stomach. It gives the stomach space to move freely while churning.

Boundaries: anterior is the liver, stomach, and lesser omentum; posterior is peritoneum on the posterior abdominal wall.

Figure 23.9.

The lesser and greater sacs communicate via the **Omental foramen (Foramen of Winslow)**, located posterior to the hepatoduodenal ligament. Place a finger in the omental foramen.

Anterior to your finger are the structures of the portal triad. Posterior to your finger is the IVC.

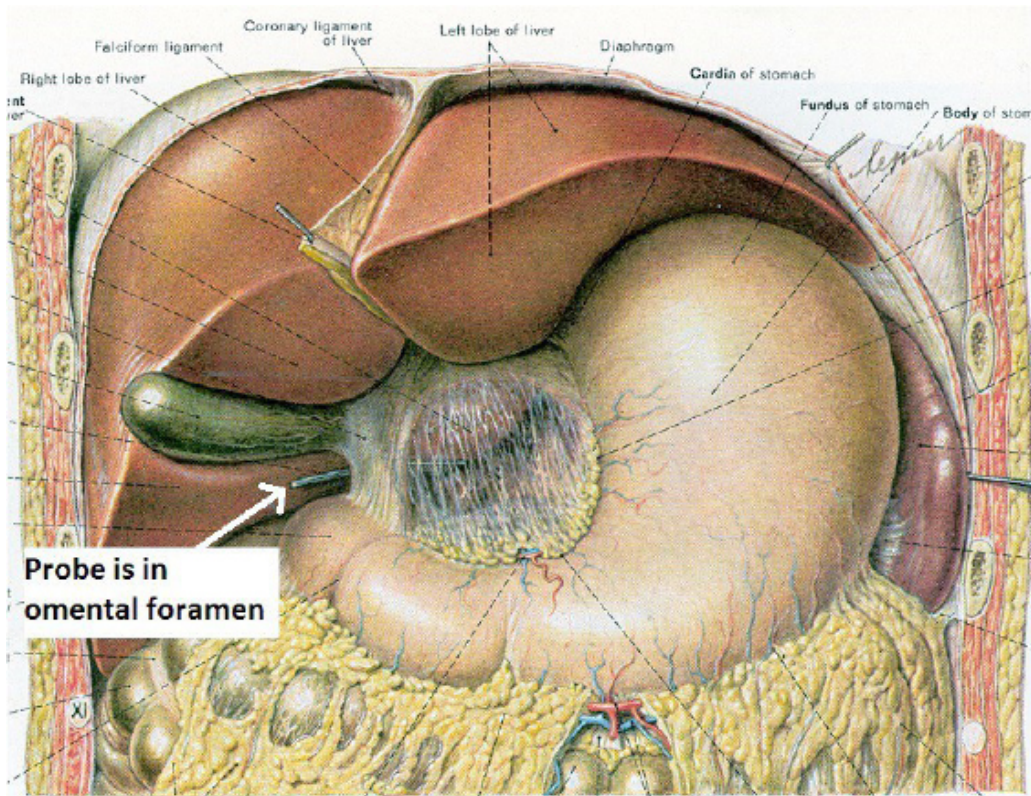

Figure 23.10. Clemente's Atlas of Anatomy.

Greater Omentum

Examine the **greater omentum**, a double-layer of peritoneum hanging down like a fatty apron from the greater curvature of the stomach.

Note

The greater omentum may adhere to areas that were previously inflamed, resulting in a constricted appearance.

Figure 23.11.

Identify its subdivisions:

- **Gastrocolic ligament** (stomach to transverse colon). This is the part that hangs from the greater curvature of the stomach like an apron.
- **Gastrosplenic ligament** (stomach to spleen)
- **Splenorenal ligament** (reach way behind the spleen to feel it with your fingertips). It is the part of the greater omentum that connects to the posterior body wall.

Figure 23.12.

The Other Mesenteries

Lift the greater omentum and identify the transverse colon. The double fold of peritoneum suspending it from the posterior abdominal wall is the **transverse mesocolon**.

Lift the **ileum** and **jejunum** and trace their **mesentery proper** to the posterior abdominal wall.

Trace the ileum to the cecum and find the **appendix**, often folded back behind the cecum. It has a small mesentery called the **mesoappendix**.

Trace the large intestine until you get to the **sigmoid colon**. It is suspended by a **sigmoid mesocolon** on the left side.

Figure 23.13.

Mesenteries, peritoneal ligaments, and omenta are all structures composed of two layers of peritoneum. Mesenteries attach to the posterior abdominal wall, while omenta attach to the stomach.

List the structures that have mesenteries, and are thus mobile, and called “intraperitoneal” organs.

Which organs had a mesentery, but then lost it during development? These organs are “secondarily” retroperitoneal.

SUPRACOLIC REGION

The transverse colon is used to divide the contents of the abdominal cavity into two areas: **supracolic region** (stomach, liver, gallbladder, pancreas, and spleen) and **infracolic region** (small intestine and large intestine). The pancreas straddles the two regions, but since it is derived from the foregut we will consider it with the other supracolic organs.

Dissect and clean structures of the portal triad.

Revisit the **omental foramen by placing a finger in it**. Anterior to it are the structures of the portal triad.

COMPLETE ANATOMY PORTAL TRIAD

Use scissors and forceps to separate and clean the structures in the **portal triad**.

- **hepatic artery proper** (anterior left side)
- **bile duct** (anterior right side)
- **portal vein** (posterior).

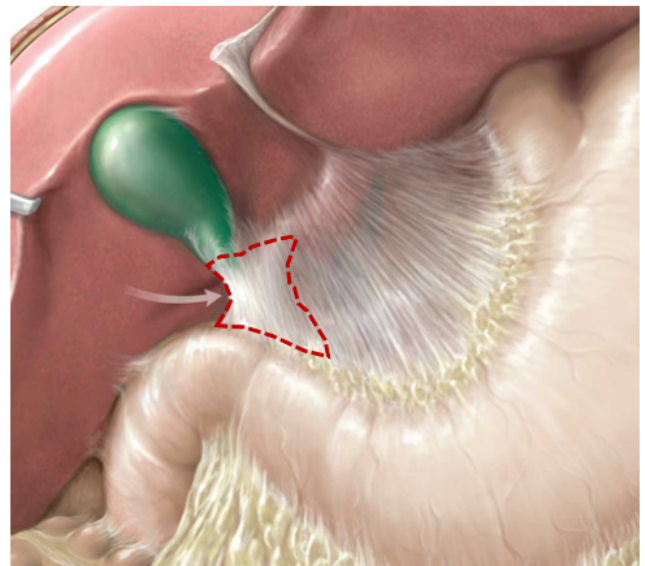

Figure 23.14.

CAREFUL!

The structures are often stained green with bile, and the vein has thin walls!

Elevate the liver and use scissors to open a window in the **lesser omentum** in the middle of the **hepatogastric ligament**. The **left** and **right gastric arteries** run along the lesser curvature of stomach within the attachment of the lesser omentum.

Now you can explore the **lesser sac** = put your fingers in the **superior recess** of the lesser sac (behind the liver) and then into the **splenic recess** to the left between spleen and stomach.

Figure 23.15.

Dissect the celiac trunk and its major branches.

This is a toughie, but we know you are up to the task. **Please study atlas figures/Complete Anatomy screens and understand the architecture of the celiac trunk and its branches before you cut!**

COMPLETE ANATOMY CELIAC TRUNK

The **celiac trunk** is the first unpaired branch of the aorta—at **T-12** just below the **aortic hiatus** of the diaphragm. **Its branches supply foregut derivatives.**

Finding the celiac trunk itself is tough since it is short and covered by peritoneum, and surrounded by a dense network of autonomic nerves (**aortic plexus**). The trick is to identify one of the three major branches (**left gastric, common hepatic, or splenic artery**), clean it, and follow it backwards to its origin from the celiac trunk.

Left Gastric Artery

Probe along the **lesser curvature of the stomach** near the esophagus to find the **left gastric artery**. Follow the left gastric artery back to the celiac trunk. Trace the **right gastric artery** along the right side of the lesser curvature.

- **Gastric arteries** anastomose within the lesser curvature of the stomach.
- **Gastro-omental arteries** anastomose along the greater curvature.

SUMMARY

Where do the gastric and gastro-omental arteries arise?

Common Hepatic Artery

Go back to the structures you just dissected in the hepatoduodenal ligament and find the **hepatic artery proper**. Trace it back to the upper border of the duodenum where it unites with the **gastroduodenal artery**. From here, clean off and follow the **common hepatic artery** to the left where it joins the celiac trunk.

Find the remaining branches of the arteries you just identified. First, find the **right gastric artery** branching from the hepatic artery proper and running towards the lesser curvature of the stomach. Next, follow the gastroduodenal artery behind the duodenum and find where it branches into the **superior pancreaticoduodenal** and right **gastroomental** branches.

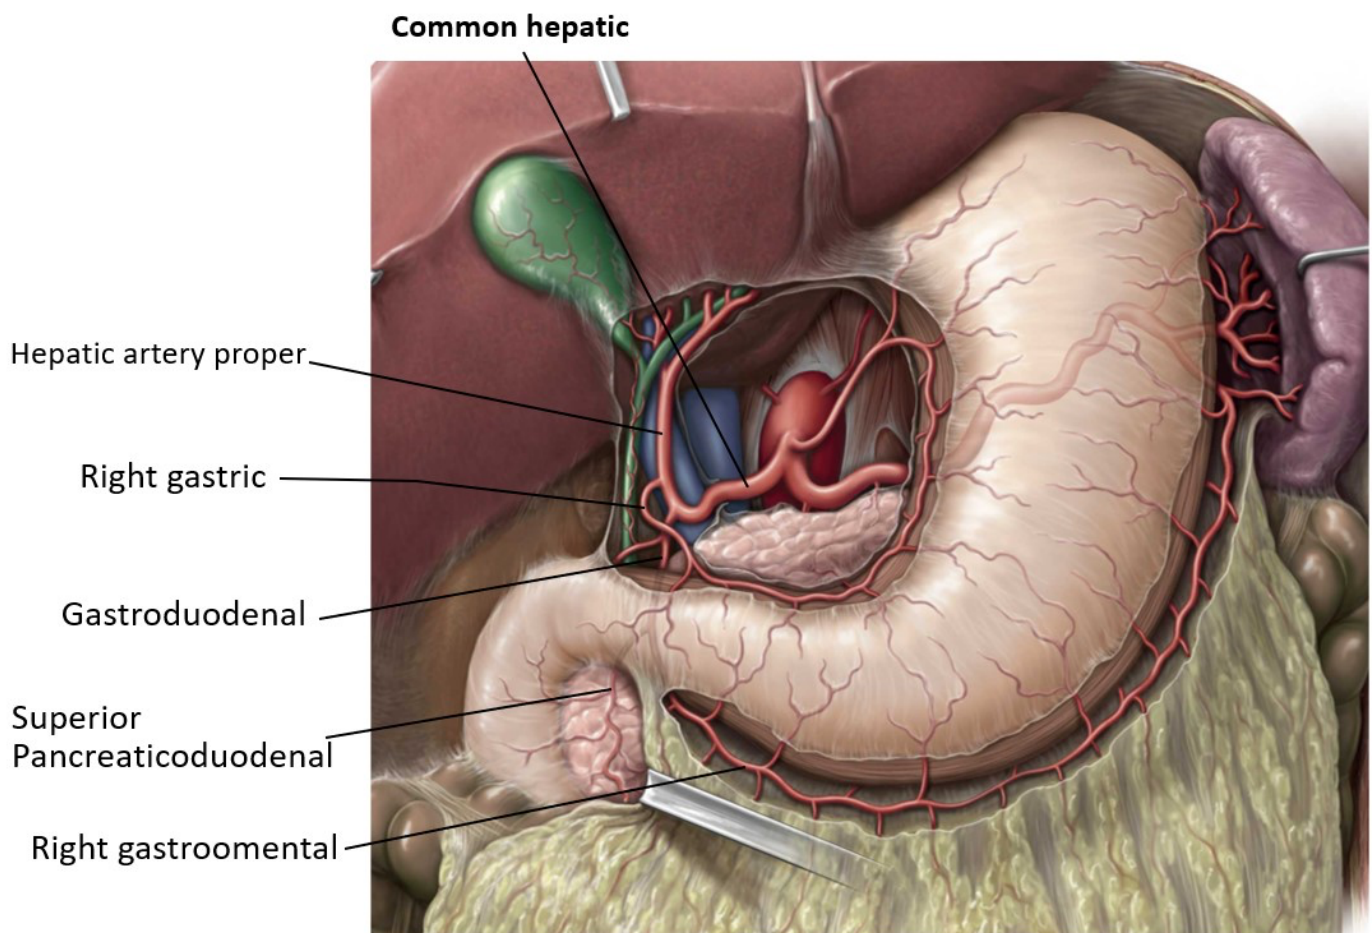

Figure 23.16.

Splenic Artery

Follow the **splenic artery**: with scissors, open a hole in the **gastrosplenic ligament** to the left of the greater curvature of the stomach. Widen the opening with your hands by tearing into the gastrocolic ligament, from left to right, below the greater curvature of the stomach (be careful not to damage the **gastro-omental arteries** running along the greater curvature!) Elevate the stomach to reach the hilum of the spleen. You should see the **pancreas** just deep to the peritoneum on the floor of the lesser sac. Clean the hilum of the spleen to find the **splenic artery**. Trace the tortuous (twisty) splenic artery to the right until you reach the celiac trunk. ***It runs along the upper border of the pancreas and may be embedded in pancreatic tissue.*** See Figure 23.17.

Figure 23.17.

Find the **left gastro-omental artery** passing from the splenic artery onto the greater curvature of the stomach (within the **gastrocolic ligament**). Keep following it, and it will merge with the right **gastro-omental artery**, which comes from the **gastroduodenal artery**.

EXAMINE FIGURE 23.18.

Your beautiful dissection should look similar to this!! Make sure you have cleaned and identified the branches of the celiac trunk before you move on.

Celiac Trunk Main Branches

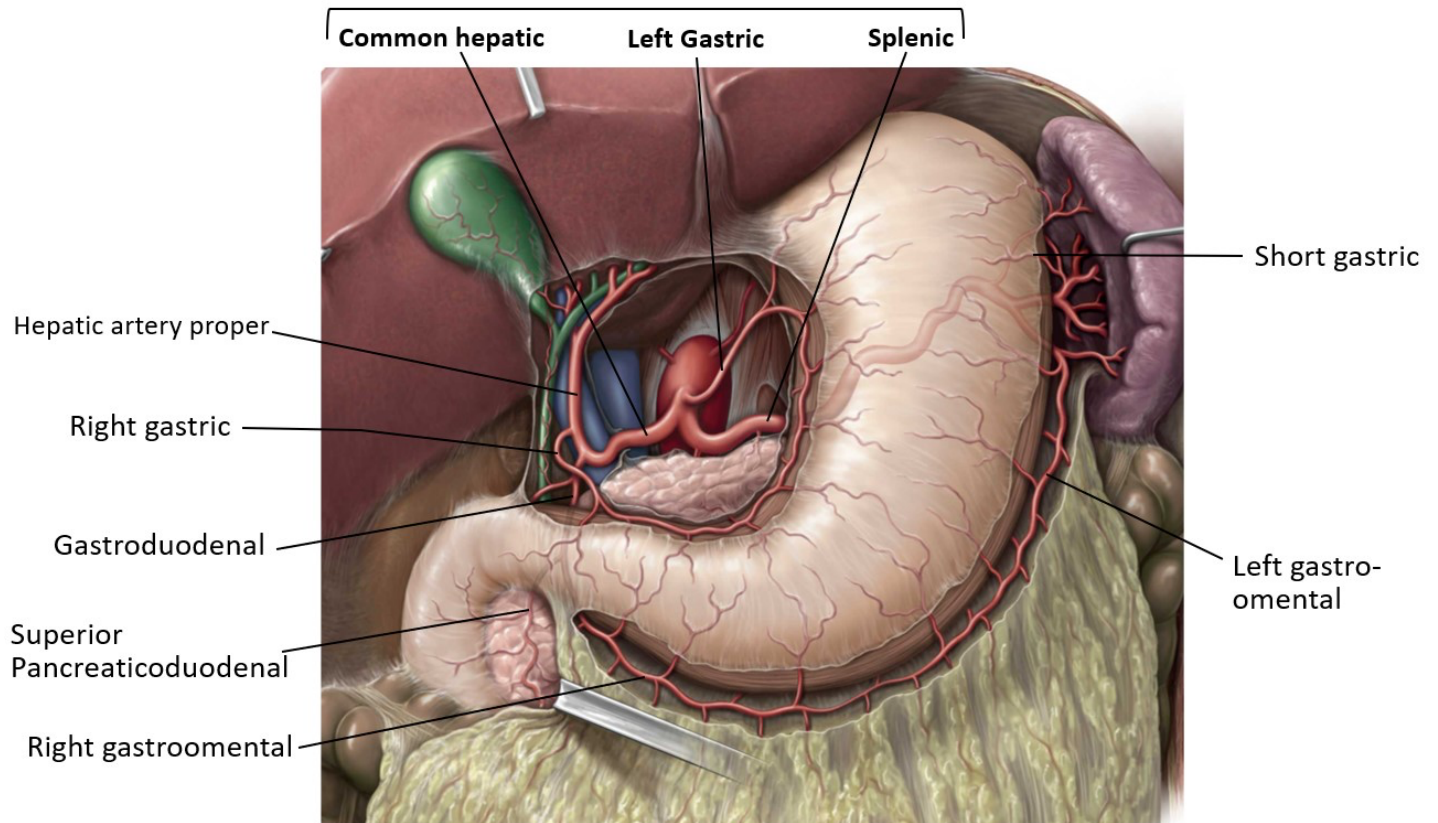

Figure 23.18.

LIVER AND GALLBLADDER

Remove the liver in order to examine its surfaces.

CHECK WITH INSTRUCTORS FIRST

We may want to keep a couple awesome portal triad dissections intact for the future.

- 1 Elevate the liver and cut the **portal triad (hepatic artery proper, bile duct, and portal vein)** near the **porta hepatis** of the liver.

Figure 23.19.

- 2 Push the liver down and use scissors to cut the **anterior layer of the coronary ligament** and the two **triangular ligaments** away from their attachments to the diaphragm. As you apply downward pressure on the liver, use blunt dissection with fingers to free up the diaphragmatic surface until you can see the **IVC** passing up into the diaphragm behind it.

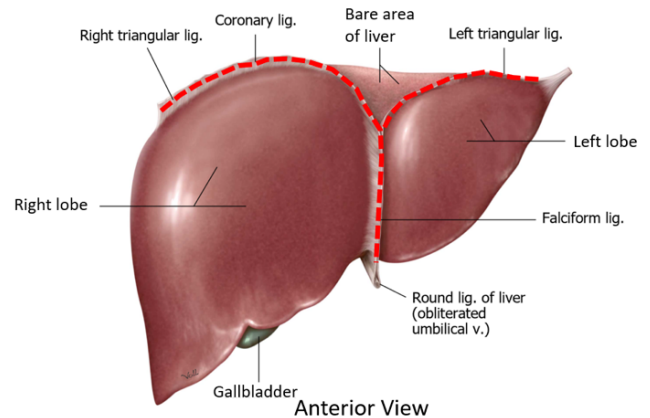

Figure 23.20.

Note

If you are having trouble, you may need to remove a few costal cartilages and some of the diaphragm for better access.

- 3 Continue to apply downward pressure as you cut the **posterior layer of the coronary ligament** behind the liver. Cut through **hepatic veins** as they enter the IVC posterior to the liver.
- 4 Try to remove the liver—if it is held up, it may be that the IVC is passing through the liver itself, in which case you will have to remove part of the IVC with the liver. **Cut through the IVC in two places:** Above the liver as it passes into the diaphragm and below the liver where the IVC is behind the omental foramen. Lift the liver out of the cadaver! Voilà!

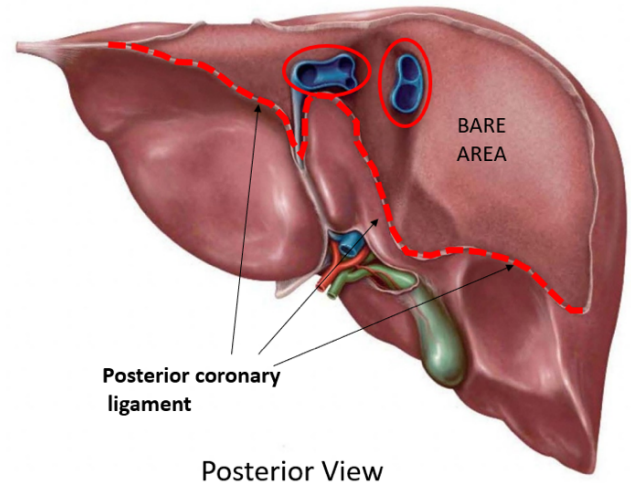

Figure 23.21.

Examine the Surfaces of the Liver

- The liver has two surfaces: **Diaphragmatic** and **Visceral**.
- The surfaces of the liver are separated by the sharp **inferior border**. The inferior border is palpated when you examine a patient's liver.

LOCATE these peritoneal structures on the diaphragmatic surface (they may not be prominent):

- **Falciform ligament**
- **Coronary ligament: Anterior and Posterior layers.** The coronary ligament perches atop the liver like a “crown,” connecting the liver to the diaphragm
- The **bare area of the liver** is between the layers of the coronary ligaments. **Why is it called “bare”?**

Anatomic Lobes of the Liver

- **Right and Left Lobes:** Best seen on the diaphragmatic surface where they are separated by the **falciform ligament**
- **Caudate and Quadrate Lobes:** Seen on the visceral surface

COMPLETE ANATOMY
VISCERAL SURFACE OF THE LIVER

FIND these landmarks/structures on the visceral surface (brought to you by the letter H):

- **Right sagittal fissure**
 - Contains the **IVC** and the fossa that contains the **gallbladder**
- **Left sagittal fissure**
 - Contains the **ligamentum venosum** and the **round ligament of the liver**
 - These ligaments are remnants of embryonic blood vessels = **which ones?**
- **Porta hepatis** (cross bar of the **H**)
- The **caudate** and **quadrate lobes** are sandwiched between the sagittal fissures

Chalk Talk

This is a good time for a Chalk Talk on the visceral surface of the liver.

Figure 23.22. Liver structures.

Review the concept of “functional” parts of the liver.

- The part of the liver to the right of the right sagittal fissure is the **functional right liver**.
- The part of the liver to the left of the right sagittal fissure is the **functional left liver**. It includes the caudate and quadrate lobes.

Turn the liver over to the visceral surface and clean structures in the porta hepatis.

Often, everything is green here, so be sure you're following your vessels.

CLEAN and FIND:

- Hepatic artery proper
 - **Right and left hepatic arteries** (be aware of variations)
 - The **cystic artery** is usually a branch of the right hepatic artery. Surgeons locate it within the **triangle of Calot**. See Figure 22.23.
- (Common) **Bile duct**
- **Common hepatic duct**
- **Cystic duct**
- **Portal vein**—the portal vein divides in the porta hepatis into left and right branches—this is one of the rare cases where a vein branches!

Figure 23.23.

GALLBLADDER

- 1 With scissors, peel away the **gallbladder** from its fossa on the visceral surface of the liver.
- 2 **EXAMINE** the gallbladder and name its parts:
 - **Fundus, Body, and Neck**
- 3 Palpate the gallbladder and see if it contains any **gallstones**. If so, open it up with scissors and see what you find!

Figure 23.24.

STOMACH

EXAMINE the **stomach** and identify its parts and relationships:

NAME these parts of the stomach:

- **Cardia, fundus, body, and pyloric part.**

SURFACE FEATURES of the stomach include:

- **Cardiac notch and Greater and Lesser Curvatures.**

Examine the stomach's relations with other organs and omental bursa:

- Anterior: diaphragm, left lobe of liver
- Posterior: lesser sac, pancreas, spleen, left kidney, and left suprarenal gland

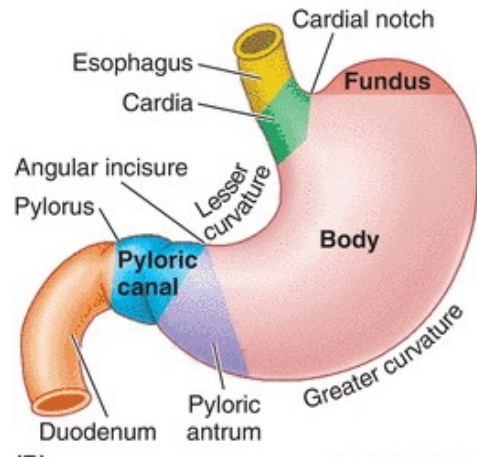

Figure 23.25.

SPLEEN

The spleen has two surfaces: **Diaphragmatic** and **Visceral**. The diaphragmatic surface is curved to conform to the underside of the diaphragm. The visceral surface contains the **hilum of the spleen** where the vessels enter.

Figure 23.26.

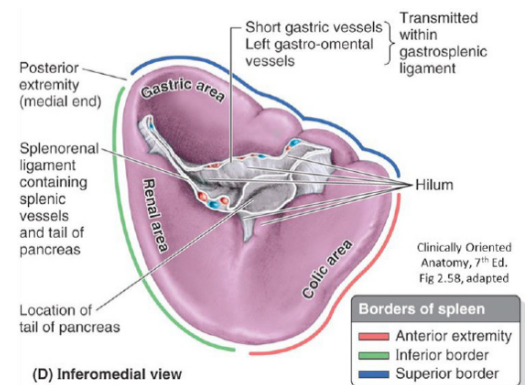

Figure 23.27.

DUODENUM AND PANCREAS

With the liver removed, clean the duodenum and pancreas.

Behind the stomach, strip the peritoneum and clean the head of the pancreas and first and second parts of the duodenum.

- 1 Clean and follow the **gastrooduodenal artery** behind the duodenum where it gives off two arteries:
 - You already found the **right gastro-omental artery** onto the greater curvature of the stomach.
 - If you didn't find it already, look for the **superior pancreaticoduodenal arteries** on the head of the pancreas. They're small, so no worries if you can't find them.

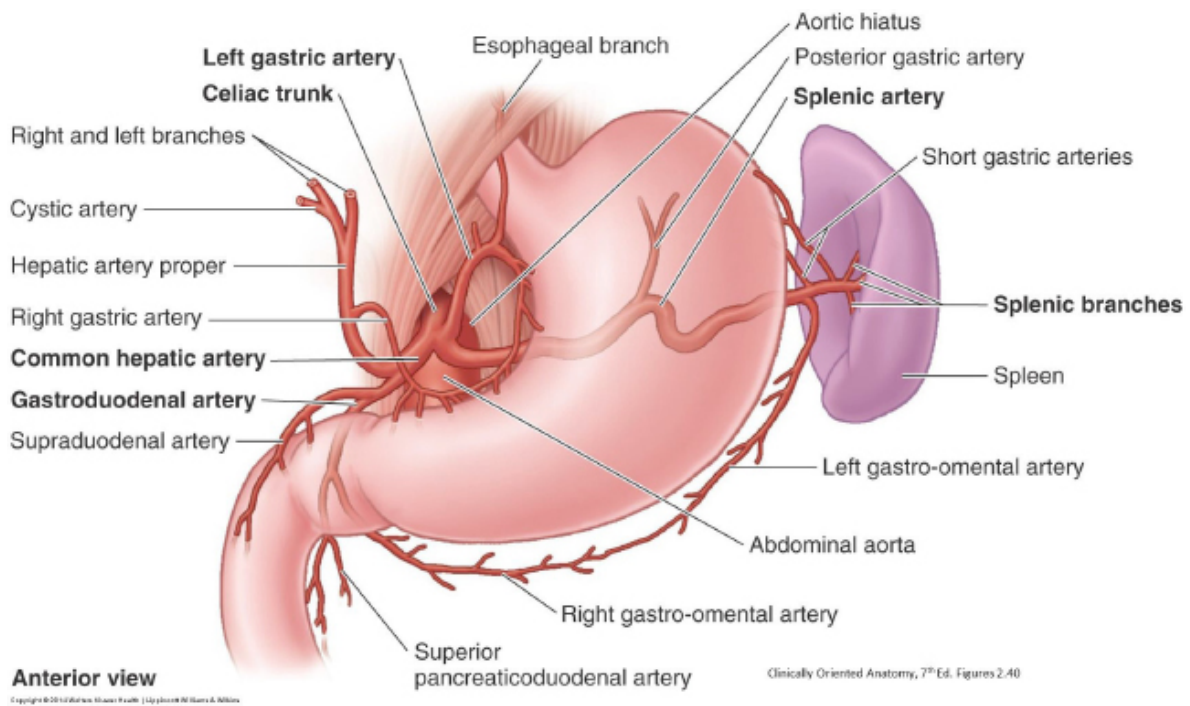

Figure 23.28.

CONCEPT

The **pancreaticoduodenal arteries** (superior from the celiac, inferior from the superior mesenteric artery) meet/ anastomose in the duodenum and head of the pancreas.

COMPLETE ANATOMY GASTRODUODENAL BRANCHES

NAME the four parts of the duodenum:

- Superior (1st part)
- Descending (2nd part)
- Inferior (horizontal, 3rd part)
- Ascending (4th part)

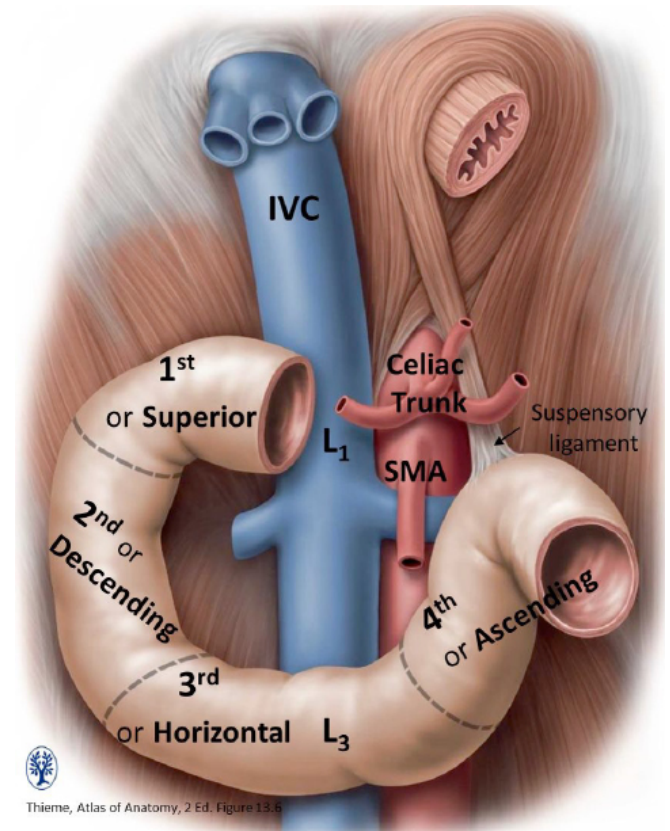

Figure 23.29.

NAME the parts of the pancreas:

- Head
- Uncinate process
- Neck
- Body
- Tail

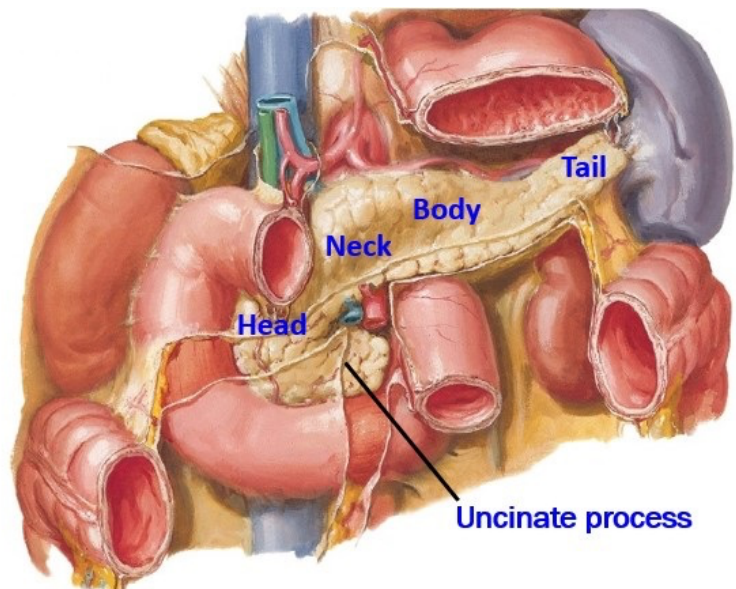

Figure 23.30.

Open the stomach and duodenum.

To study the internal anatomy of the duodenum, first examine [Figure 23.31](#), then follow these steps:

- 1 Open the anterior wall of the body of the stomach with scissors. Clean out gastric contents to find **gastric folds (rugae)**. These are **temporary folds** that flatten out as the stomach fills.
- 2 Make a horizontal incision through the junction of the stomach and duodenum to see the **pyloric sphincter**.
- 3 With a vertical incision, open the entire length of the descending duodenum. Observe the **circular folds**. These are **permanent folds** that help to increase the absorptive surface area.

Dissect out the pancreatic and bile ducts.

COMPLETE ANATOMY BILE AND PANCREATIC DUCTS

Follow the **bile duct** inferiorly behind the superior duodenum and head of the pancreas. Use scissors and forceps to carve away pancreatic tissue to locate the union of the bile duct and **main pancreatic duct** in the head of the pancreas, medial to the descending part of the duodenum. The (common) bile duct and main pancreatic duct unite in a muscular chamber: the **hepatopancreatic ampulla**.

Note

Sphincters are present in the distal part of the bile duct (the **Choledochal sphincter**), and in the hepatopancreatic ampulla (**Sphincter of Oddi**). You won't see these but know where they are located.

The ampulla causes an internal bulge in the mucosa within the lumen of the descending duodenum (2nd part). This bulge is the **major duodenal papilla**; look in the duodenum to see if you can locate this. Both bile from the liver and digestive enzymes from the pancreas enter the duodenum through the orifice atop the major duodenal papilla.

Figure 23.31.

CHECKLIST, LAB #23

REVIEW AND MAKE SURE YOU HAVE IDENTIFIED EACH OF THE STRUCTURES BELOW.

INTERNAL ASPECT OF ANTERIOR ABDOMINAL WALL

- Median umbilical fold w/ligament (urachus)
- Medial umbilical folds w/ligament (obliterated umbilical arteries)
- Inferior epigastric vessels

PERITONEUM AND PERITONEAL CAVITY

- Parietal and visceral peritoneum
- Peritoneal cavity
- Greater sac
 - Subphrenic spaces
 - Hepatorenal recess
 - Paracolic gutters
 - Retrocecal recess
 - Rectovesical pouch (in pelvis—male)
 - Recto-uterine and uterovesical pouches (in pelvis—female, when uterus is present)
- Lesser sac
- Omental foramen
- Lesser omentum
 - Hepatoduodenal ligament
 - Hepatogastric ligament
- Greater omentum
 - Gastrocolic ligament
 - Gastrosplenic ligament
 - Splenorenal ligament
- Mesentery of the small intestine
- Transverse mesocolon
- Sigmoid mesocolon

DETAILS OF SUPRACOLIC STRUCTURES

- Abdominal esophagus
- Liver
 - Diaphragmatic & visceral surfaces
 - Anatomic Lobes: right, left, caudate, quadrate
 - Right and left sagittal fissures
 - Porta hepatis
 - Coronary ligament of liver (anterior & posterior layers)
 - Bare area of liver
 - Falciform ligament
 - Ligamentum venosum (vestige of ductus venosus)
 - Round ligament of liver (vestige of umbilical vein)
- Gallbladder
 - Fundus, Body, and Neck
- Cystic duct
- Common hepatic duct
- Common bile duct
- Portal vein
- Portal triad = hepatic artery proper, bile duct, and portal vein
- Stomach
 - Cardia & cardiac notch
 - Fundus and Body
 - Greater and Lesser curvatures

- Pyloric part with pyloric sphincter
- Gastric folds (rugae)
- Duodenum = 4 parts
 - Superior (1st part), descending (2nd part), inferior/horizontal (3rd part), and ascending (4th part)
- Pancreas
 - Head w/uncinate process
 - Neck, Body, and Tail
- Bonus points for locating the Main pancreatic duct
- Hepatopancreatic ampulla (= union of Bile duct + Main pancreatic duct)
- Major duodenal papilla
- Spleen: visceral and diaphragmatic surfaces
- Celiac trunk
 - Left gastric artery
 - Splenic artery
 - Left gastro-omental artery
 - Common hepatic artery
 - Right gastric artery (can be quite small . . . so bonus points if you find it)
 - Gastroduodenal artery
 - Right gastro-omental artery
- Hepatic artery proper
 - Right & left hepatic arteries
 - Bonus points for cystic artery (supplies gallbladder—usually a branch of the right hepatic artery)
